

Taproot in the Generic Group Model

Lloyd Fournier (lloyd.fourn@gmail.com)

Introduction

BIP-340 (Schnorr) and BIP-341 (Taproot) are proposed upgrades to the Bitcoin network that create a new type of public key output which can be spent by (i) a Schnorr signature under that public key or (ii) revealing a hidden commitment to a script *inside* the public key and satisfying the conditions of the script. Framed as a hybrid commitment scheme:

TapCom(G, m)	TapOpen($G, \text{com}_{pk}, \text{open}$)
$x \leftarrow \mathbb{Z}_q; X \leftarrow xG$	$(X, m) := \text{open}$
$y \leftarrow H(f(X) m); Y \leftarrow yG$	if $X + H(f(X) m)G = \text{com}_{pk}$
$\text{com}_{pk} \leftarrow X + Y$	return m
open $:= (X, m)$	else return \perp
$sk \leftarrow x + y$	
return $(sk, (\text{com}_{pk}, \text{open}))$	

If the hash function H is idealised as a random oracle then the scheme is secure[1]. Taking inspiration from [2], we instead idealise the elliptic curve group in the *Generic Group Model* to isolate what properties the hash function requires for Taproot to be secure. To compute new group elements the adversary is allowed up to q_G queries to the oracle \mathcal{G} with two elements it already knows (G_1, G_2). The oracle returns a new group element G_3 representing $G_1 - G_2$.

The main hash function properties we consider are:

- Random-Prefix Preimage Resistance (RPP): Strictly weaker assumption than collision resistance. Already required for Schnorr[2].
- Chosen Offset Prefix Collision Resistance (COPC): New assumption for Taproot's binding as commitment scheme. Breaking seems unrelated to collision resistance.

RPP	COPC
$(\text{st}, h) \leftarrow \mathcal{A}$	$P_1 \leftarrow \mathcal{P}$
$P \leftarrow \mathcal{P}$	$(\text{st}, \delta) \leftarrow \mathcal{A}(P_1)$
$m^* \leftarrow \mathcal{A}(\text{st}, P)$	$P_2 \leftarrow \mathcal{P}$
return $H(P m^*) = h$	$(m_1, m_2) \leftarrow \mathcal{A}(\text{st}, P_2)$
	return $H(P_1 m_1) - H(P_2 m_2) = \delta$

Forging an Opening

Can an adversary forge a fake opening on someone else's coins? Call this the *Taproot Forge* problem (TF). RPP is necessary for TF to be hard:

TF	$\mathcal{R} : \text{TF} \rightarrow \text{RPP}$
$(\text{st}, m_1) \leftarrow \mathcal{A}$	<div style="border: 1px dashed black; padding: 5px; display: inline-block;">m_1 <i>Challenger</i></div>
$G \leftarrow \mathbb{G}$	<div style="border: 1px dashed black; padding: 5px; display: inline-block;">$G, \text{com}_{pk}, \text{open}$</div>
$(\cdot, (\text{com}_{pk}, \text{open})) \leftarrow \text{TapCom}(G, m)$	$(h, \text{st}) \leftarrow \mathcal{A}_{\text{RPP}}; T := \text{com}_{pk}$
$(X^*, m_2) \leftarrow \mathcal{A}(\text{st}, G, \text{com}_{pk}, \text{open})$	$C \leftarrow T - hG; P \leftarrow f(C)$
return $X^* + H(f(X^*) m_2)G = \text{com}_{pk}$ $\wedge m_2 \neq m_1$	$m_2 \leftarrow \mathcal{A}_{\text{RPP}}(\text{st}, P)$
	return (C, m_2)

To show RPP is sufficient, \mathcal{R} guesses which query to \mathcal{G} will be used for the malicious *Taproot internal key*, C .

$\mathcal{R} : \text{RPP} \rightarrow \text{TF}$	Simulate $\mathcal{G}(G_1, G_2)$
$(\text{st}, m_1) \leftarrow \mathcal{A}_{\text{TF}}$	$(a_1, b_1) \leftarrow \mathcal{L}[G_1]; (a_1, b_1) \leftarrow \mathcal{L}[G_2]$
$(G, X, T) \leftarrow \mathbb{G}^3$	$(a_3, b_3) \leftarrow (a_1 - a_2, b_1 - b_2)$
$x \leftarrow \mathbb{Z}_q$	if $\exists(\cdot, a_i, b_i) \in \mathcal{L} \mid a_i + b_i x = a_3 + b_3 x$
$y \leftarrow H(f(X) m_1)$	abort
$t \leftarrow x + y$	else if $i_0 = i$
$\mathcal{L} := \{(G, 1, 0), (X, 0, 1), (T, y, 1)\}$	$h \leftarrow t - (a_3 + b_3 x)$
$i_0 \leftarrow \{1, 2, \dots, q_G\}; i \leftarrow 1$	<div style="border: 1px dashed black; padding: 5px; display: inline-block;">h <i>Challenger</i></div>
$(X^*, m_2) \leftarrow \mathcal{A}_{\text{TF}}^{\mathcal{G}}(\text{st}, G, T, (X, m_1))$	<div style="border: 1px dashed black; padding: 5px; display: inline-block;">P</div>
if $X^* = \tilde{X}$	$\tilde{X} \leftarrow f^{-1}(P); G_3 := X$
$\parallel \Rightarrow X^* + H(P m_2)G = T$	else $G_3 \leftarrow \mathbb{G}$
$\parallel \Rightarrow H(P m_2) = h$	$\mathcal{L} := \mathcal{L} \cup \{(G_3, a_3, b_3)\}$
return m^*	$i \leftarrow i + 1$
else return \perp	return G_3

MuSig with Covert Taproot

Can an adversary come up with a covert Taproot spend by choosing their MuSig public key maliciously? Call this the *MuSig Covert Taproot* (MCT) problem.

MCT	MuSig(X_1, X_2)
$X_1 \leftarrow \mathbb{G}$	$L := (X_1, X_2)$
$(X_2, (C, m)) \leftarrow \mathcal{A}(X_1)$	$c_1 \leftarrow H_{\text{agg}}(L, X_1)$
$X \leftarrow \text{MuSig}(X_1, X_2)$	$c_2 \leftarrow H_{\text{agg}}(L, X_2)$
return $X = C + H(f(C) m)G$	return $c_1 X_1 + c_2 X_2$

RPP is sufficient to ensure MCT is hard if X_2 is queried before C . If the reduction guesses correctly which queries will be used for X_2 and C it solves RPP. This approach only works for 2-party MuSig.

$\mathcal{R} : \text{RPP} \rightarrow \text{MCT}$	Simulate $\mathcal{G}(G_1, G_2)$
$x_1 \leftarrow \mathbb{Z}_q; (G, X_1) \leftarrow \mathbb{G}^2$	$(a_1, b_1) \leftarrow \mathcal{L}[G_1]; (a_2, b_2) \leftarrow \mathcal{L}[G_2]$
$(i_0, i_1) \leftarrow \{1, 2, \dots, q_G\} \text{ s.t. } i_0 < i_1$	$(a_3, b_3) \leftarrow (a_1 - a_2, b_1 - b_2)$
$\mathcal{L} := \{(G, 1, 0), (X_1, 0, 1)\}$	if $\exists(\cdot, a_i, b_i) \in \mathcal{L} \mid a_i + b_i x_1 = a_3 + b_3 x_1$
$(X_2, (C, m)) \leftarrow \mathcal{A}_{\text{RPP}}^{\mathcal{G}}(G, X_1)$	abort
if $X_2 = \tilde{X}_2 \wedge C = \tilde{C}$	else if $i = i_0$
$\parallel \Rightarrow \text{MuSig}(X_1, X_2) = C + H(P m)G$	$\tilde{X}_2 \leftarrow \mathbb{G}; \tilde{x}_2 \leftarrow a_3 + b_3 x_1; G_3 := \tilde{X}_2$
$\parallel \Rightarrow H(P m) = h$	else if $i = i_1$
return m	$L := (X_1, \tilde{X}_2)$
else	$x \leftarrow H_{\text{agg}}(L, X_1)x_1 + H_{\text{agg}}(L, \tilde{X}_2)\tilde{x}_2$
return \perp	$h \leftarrow x - (a_3 + b_3 x_1)$
	<div style="border: 1px dashed black; padding: 5px; display: inline-block;">h <i>Challenger</i></div>
	<div style="border: 1px dashed black; padding: 5px; display: inline-block;">P</div>
	$\tilde{C} \leftarrow f^{-1}(P); G_3 := \tilde{C}$
	else $G_3 \leftarrow \mathbb{G}$
	$\mathcal{L} := \mathcal{L} \cup \{(G_3, a_3, b_3)\}$
	$i \leftarrow i + 1$
	return G_3

If C is queried before X_2 , or $C = X_2$ then (I think) \mathcal{A} can be used to break Preimage Resistance.

MuSig Second Covert Taproot

Can an adversary create a second malicious Taproot spend in addition to an agreed upon one by choosing their parameters maliciously? Call this the *MuSig Second Covert Taproot* (MSCT) problem. COPC is necessary for MSCT to be hard:

MSCT	$\mathcal{R}(X_1) : \text{MSCT} \rightarrow \text{COPC}$
$X_1 \leftarrow \mathbb{G}$	$X_2 \leftarrow \mathbb{G}$
$(X_2, m_1, (C, m_2)) \leftarrow \mathcal{A}(X_1)$	$X \leftarrow \text{MuSig}(X_1, X_2); P_1 \leftarrow f(X)$
$X \leftarrow \text{MuSig}(X_1, X_2)$	$(\text{st}, \delta) \leftarrow \mathcal{A}(P_1)$
$\text{com}_{pk} \leftarrow X + H(f(X) m_2)$	$C \leftarrow X - \delta G; P_2 \leftarrow f(C)$
return $\text{com}_{pk} = C + H(f(C) m_2)$ $\wedge m_2 \neq m_1$	$(m_1, m_2) \leftarrow \mathcal{A}(\text{st}, P_2)$
	return $(X_1, m_1, (C, m_2))$

COPC is sufficient to make MSCT hard where the Taproot internal keys for are not the same i.e $X \neq C$. If the reduction guesses which queries will be used for X and C correctly (in any order) it solves COPC.

$\mathcal{R}(P_1) : \text{COPC} \rightarrow \text{MSCT}$	Simulate $\mathcal{G}(G_1, G_2)$
$D_1 \leftarrow f^{-1}(P_1)$	$(a_1, b_1) \leftarrow \mathcal{L}[G_1]; (a_2, b_2) \leftarrow \mathcal{L}[G_2]$
$x_1 \leftarrow \mathbb{Z}_q; (G, X_1) \leftarrow \mathbb{G}^2$	$(a_3, b_3) \leftarrow (a_1 - a_2, b_1 - b_2)$
$(i_0, i_1) \leftarrow \{1, 2, \dots, q_G\} \text{ s.t. } i_0 < i_1$	if $\exists(\cdot, a_i, b_i) \in \mathcal{L} \mid a_i + b_i x_1 = a_3 + b_3 x_1$
$i \leftarrow 1$	abort
$\mathcal{L} := \{(G, 1, 0), (X_1, 0, 1)\}$	else if $i = i_0$
$(X_2, m_1, (C, m_2)) \leftarrow \mathcal{A}_{\text{MSCT}}^{\mathcal{G}}(G, X_1)$	$d_1 \leftarrow a_3 + b_3 x_1$
$X \leftarrow \text{MuSig}(X_1, X_2)$	$G_3 := D_1$
if $X = D_1 \wedge C = D_2$	else if $i = i_1$
$\parallel X + H(P_1 m_1)G = C + H(P_2 m_2)G$	$d_2 \leftarrow a_3 + b_3 x_1$
return (m_1, m_2)	$\delta \leftarrow d_1 - d_2$
else if $X = D_2 \wedge C = D_1$	<div style="border: 1px dashed black; padding: 5px; display: inline-block;">δ <i>Challenger</i></div>
$\parallel X + H(P_2 m_1)G = C + H(P_1 m_2)G$	<div style="border: 1px dashed black; padding: 5px; display: inline-block;">P_2</div>
return (m_2, m_1)	$D_2 \leftarrow f^{-1}(P_2); G_3 := D_2$
else return \perp	else $G_3 \leftarrow \mathbb{G}$
	$\mathcal{L} := \mathcal{L} \cup \{(G_3, a_3)\}$
	$i \leftarrow i + 1$
	return G_3

If $X = C$, then \mathcal{A} clearly breaks collision resistance.

Remarks

- These reductions are incomplete – they do not account for \mathcal{A} choosing G or X_1 etc as one of the elements they return. They can be modified to fix this.
- To actually steal coins, the malicious Taproot openings have to be valid Merkle Root (m can't be arbitrary).
- If coin tossing is used to generate joint key instead of MuSig then security in all scenarios follows from RPP.
